# An Algorithm for a Special Class of Generalized Transportation-Type Problems

by Ronald L. Arms

MCLEAN, VIRGINIA

#### **FOREWORD**

This paper describes an algorithm developed for solving a special class of generalized transportation-type problems of moderate size. Problems concerned with optimal aliocations of resources subject to meeting a given set of requirements such as marketing, routing, production, and weapons allocation are frequently of the generalized transportation type.

The generalized transportation-type problem considered here is a linear programming problem with solutions giving the allocations  $x_{ij}$  of the jth resource to the ith operation such as to maximize a given profit function. The requirements specify the limits on each of the n available resources as well as the operational limits of each of the m operations. In addition the operational capacity of the ith operation when the jth resource is assigned to it is known. The structure of such problems (one constraint for each row i and each column j) enables an algorithm more efficient than the general simplex algorithm to be used for finding a solution.

The algorithm is intended to solve moderate-sized problems faster than will general simplex algorithms. It requires less computer storage than general simplex algorithms, thus making it particularly useful when a limited-capacity computer memory is all that is available.

Nicholos M. Smith Head, Advanced Research Department

#### **ACKNOWLEDGMENTS**

The author wishes to acknowledge the encouragement of Dr. Jerome Bracken and Dr. Frederick Miercort in developing the algorithm for application to part of RAC's Nike X study and to thank Drs. D. Gross, C. M. Harris, and J. D. Pearson for their reviews, criticisms, and suggestions, which have largely been incorporated in the present version of the paper.

# An Algorithm for a Special Class of Generalized Transportation-Type Problems

#### **ABSTRACT**

The algorithm described in this paper is used to solve a special class of linear programming problems characterized by constraint coefficient matrices having generalized transportation structure. Specifically, n available resources are allocated to m capacity-limited operations (where the operational capability of assigning the jth resource to the ith operation is known) such as to maximize the total profit for the system. The row-and-column structure of such problems permits an algorithm more efficient than the general simplex algorithm to be used to solve moderate-sized problems (problems where loop-tracing techniques or equivalent schemes are not required). It is not required in the problem statement that all the resources be allocated or that all operations be performed to capacity limits. It is characteristic of such problems, however, that the optimizing solution usually requires that at least one of the two conditions holds, i.e., either supply or demand is exhausted. The paper contains a description of the algorithm, a computer program, an example illustrating its application, and some comparisons with the general simplex algorithm in solving the same problem.

#### 1. INTRODUCTION

The algorithm presented here yields optimal solutions to a special class of linear programming problems that are characterized by constraint coefficient matrices having generalized transportation structure. † The algorithm preserves primal feasibility and the complementary slackness condition at all times; hence feasibility of the dual constraints forms a set of necessary and sufficient conditions for testing optimality.

The need for the present algorithm arose initially in application to an optimal weapons-allocation problem as part of a larger nonlinear minimax problem employed in an earlier RAC study<sup>1</sup> in this area.

A specialized algorithm (similar to the one given here) for generalized transportation-type problems appears to have been first used by Ferguson and Dantzig.<sup>2,3</sup>

The algorithm can be divided computationally into two phases: (1) the matrix maximum phase and (2) the simplex phase. In phase 1 the algorithm permits only vectors associated with positive cost to enter the basis and only basis vectors associated with slack variables to leave the basis. In phase 2 the selection of the next neighboring vertex is currently made as it is done in most simplex algorithms (see Ref 4, Lecture V and the appendix).

The particular structure of the constraint coefficient matrix permits economy of computation by employing the equivalent of a doubly indexed simplex algorithm.

#### 2. PROBLEM STATEMENT

The algorithm presented in subsequent sections yields an optimal solution to the following class of linear programming problems.

†The details of this structure will be considered in Sec 3, "Problem Structure."

Maximize

$$\sum_{i,j}^{m,n} c'_{ij} x'_{ij} \qquad \text{with respect to} \qquad x'_{ij}$$

subject to the constraints

$$\sum_{j=1}^{m} d'_{ij} x'_{ij} \leq a_{i}, a_{i} > 0 ; (i = 1, ..., m)$$

$$\sum_{i=1}^{m} h'_{ij} x'_{ij} \leq b_{j}, b_{j} > 0 ; (j = 1, ..., m)$$

$$x'_{ij} \geq 0$$

$$c'_{ij} \geq 0$$

$$d'_{ij}, h'_{ij} > 0$$

$$(j = 1, ..., m)$$

$$(j = 1, ..., m)$$

Under the correspondences

$$x_{ij} = h'_{ij}x'_{ij}$$

$$d_{ij} = d'_{ij}/h'_{ij}$$

$$c_{ij} = c'_{ij}/\bar{h}'_{ij}$$
(2)

an optimal solution to Prob 1 can be found from finding an optimal solution to Prob 3.

Maximize

$$\sum_{i,j}^{m,n} c_{ij} x_{ij} \qquad \text{with respect to} \qquad x_i$$

subject to the constraints

$$\sum_{j=1}^{n} d_{ij} x_{ij} \leq a_{i}, a_{i} > 0 ; (i = 1, ..., m)$$

$$\sum_{i=1}^{m} x_{ij} \leq b_{j}, b_{j} > 0 ; (j = 1, ..., m)$$

$$x_{ij} \geq 0$$

$$c_{ij} \geq 0$$

$$d_{ii} > 0$$

$$(i = 1, ..., m)$$

$$(j = 1, ..., m)$$

The algorithm finds an optimal solution to Prob 3.

It should be observed that <u>both</u> the row and column constraints are inequalities. It is characteristic of such problems that the optimizing solution has the property that either all the row constraints, or all the column constraints, or both all row and all column constraints are binding when all  $c_{ij} > 0$ . If equalities are imposed on the column constraints and the row inequalities are of either type, we have the generalized transportation problem considered by Hadley.<sup>5</sup>

If both row and column constraints are equalities,  $\sum a_i = \sum b_j$ , and  $d_{ij} = 1$  for all i, j, the problem reduces to the standard transportation problem.

#### 3. PROBLEM STRUCTURE: GENERAL DISCUSSION

The general simplex algorithm may be used to solve Probs 1 or 3. For large m and n, however, it is not practical to do so. Writing the components  $x_{ij}$  of  $x \in E^{mn}$  using a single component subscript index k for  $x_k$  (as is done when using the general simplex algorithm), we see that the constraint matrix A contains mn(m + n - 2) zeros.

If g is the component subscript indexing function [g(i, j) = k] for the vector x, then for the problem

$$\max_{\mathbf{x}} \langle c, \mathbf{x} \rangle \quad \mathbf{x} \in \mathbf{E}^{mn} \quad c \in \mathbf{E}^{mn}$$

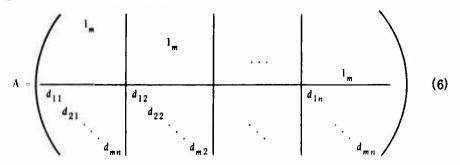

$$A_{\mathbf{x}} \leq \mathbf{b} \quad \mathbf{b} \in \mathbf{E}^{m+n} \quad \mathbf{b} > 0$$

$$\mathbf{x} \geq \mathbf{0}$$
(4)

A assumes either of the two structures

when  $g(i,j) = n(i-1) + j = k (1 \le i \le m, 1 \le j \le n)$ 

where  $l_n$  is the identity matrix of order n or

when  $g(i,j) = m(j-1) + i = k (1 \le j \le n, 1 \le i \le m)$ 

where 1<sub>m</sub> is a row vector of m ones.

†The right-hand side column vector b here includes m + n components  $(m \ a_i \text{ and } n \ b_j)$  as in Prob 3.

Any other indexing by g (besides interchanging upper and lower blocks) produces a less uniform structure for A. Structure 5 for A is associated with generalized transportation-type problems. When all  $d_{ij}=1$  the structure of A in Structure 5 is that of coefficient matrices associated with transportation problems. Structure 5 for A will be assumed when introducing suitable basis vectors for the solution space later on.

#### 4. OPTIMALITY CRITERIA

The algorithm preserves primal feasibility P and the complementary slackness condition S at all times and uses the feasibility of the dual-programming problem constraints D as the optimality test criterion.

The three sets of Conditions P, D, and S are explicitly

$$P: \begin{cases} Ax + I_{m+n}x_s = b \\ x \ge 0 \\ x_s \ge 0 \end{cases} \qquad D: \begin{cases} A'w - I_{mn}w_s = c \\ w_s \ge 0 \\ w \ge 0 \end{cases}$$

$$(7)$$

S: 
$$\langle w, x_s \rangle + \langle w_s, x \rangle = 0$$

where 'denotes transposition

⟨ , ⟩ denotes inner product

b > 0

RAC

c > 0

See Ref 6, Pt 2, p 58, for a discussion of Conditions 7.

Real vectors x, w that satisfy Conditions P, D, and S also solve the pair of dual linear programming problems

$$\max_{\mathbf{x}} \langle c, \mathbf{x} \rangle \quad \text{subject to P} \tag{8a}$$

$$\min_{w} \langle w, b \rangle$$
 subject to D (8b)

Problem 8a is solved with Conditions P and S always holding, hence Condition D becomes the set of necessary and sufficient conditions for optimality.

In practice the algorithm enforces the following stronger form  $\bar{S}$  of Condition S, namely,

$$\langle w, x_s \rangle + \langle w_s, x \rangle = 0$$
 at the component level, (75)

i.e.,  $x_{ij} > 0 \Rightarrow w_{s_{ij}} = 0$ ;  $x_{s_i} > 0 \Rightarrow w_i = 0$ . Since the dual space constraint  $A'w - I_{mn}w_s = c$  holds for all  $w, w_s$  throughout the algorithm, Conditions  $7\overline{D}$  become the set of necessary and sufficient conditions for optimality, i.e.,

$$w_s \geq 0$$
,  $w \geq 0$  (7 $\overline{\mathbf{D}}$ )

#### 5. PROCESSES OF THE ALGORITHM

The general processes of the algorithm, the details of which will follow, are

- (1) Generate basic primal feasible solution using complete or partial matrix maximum (Conditions 7P are satisfied by exactly m + n positive primal variables  $x, x_s$  while the primal objective function is increased).
- (2) Solve for the dual space variables  $u_i$  and  $v_j$  using Condition  $7\overline{S}$  and knowledge of the structure of basis vectors associated with the positive primal variables.
- (3) Perform optimality test (test Conditions  $7\overline{D}$ ). If there are no violations the current basic primal solution is optimal.
- (4) For nonoptimal solutions find the largest violation of Conditions  $7\overline{D}$ . Identify the associated vector for entry into the basis for the primal solution space.
- (5) Find the representation of the entering vector in terms of vectors in current basis.
- (6) Preserving primal feasibility Conditions P, select vector to leave the current basis.
  - (7) Express the solution in terms of the new basis.
  - (8) Return to step 2.

#### 6. DETAILS OF THE ALGORITHM

The detailed description of the steps of the algorithm is presented here.

#### 1. Generation of Basic Primal Feasible Solutions

The matrix maximum method of generating solutions  $x_{ij}$  is a process that makes allocations (assigns values to  $x_{ij}$ ) to payoff elements  $c_{ij}$  of a matrix  $\overline{P}$  of payoffs as follows:

Let

$$P = \{c_{ij} | x_{in'} \neq 0 \text{ and } x_{m'j} \neq 0\} \qquad (i = 1, ..., n)$$

$$(j = 1, ..., m)$$

$$n' = n + 1$$

$$m' = m + 1$$
(9)

where

$$x_{in'} = a_i - \sum_{j=1}^{n} d_{ij} x_{ij}$$
$$x_{m'_j} = b_j - \sum_{i=1}^{m} x_{ij}$$

 $x_{in'}$  and  $x_{m'j}$  represent the residual "slack" in row i and column j (Prob 3) after a set  $\{x_{ij}\}$  of allocations has been made. In Conditions 7  $x_s = (x_{1n'}, \ldots, x_{mn'}, x_{m'1}, \ldots, x_{m'n})'$ . If either  $x_{in'}$  or  $x_{m'j} = 0$  then no further allocations involving row i or column j can be made since either the ith capacity has been achieved or the jth resource exhausted. Initially  $\overline{P}$  is the matrix of all  $c_{ij}$  since  $x_{in'} = a_i$  and  $x_{m'j} = b_j$ .

For each allocation  $x_{ij}$  of the matrix maximum method let

$$c_{k|l} = \max_{i,j} |c_{ij}| c_{ij} \in \overline{P}!$$
 (10)

then choose

$$x_{k\ell} = \min \left\{ \frac{a_{k} - \sum_{j=1}^{m} d_{kj} x_{kj}}{d_{k\ell}} : b_{\ell} - \sum_{i=1}^{n} x_{i\ell} \right\}$$

$$= \min \left\{ \frac{x_{km'}}{d_{k\ell}} : x_{m'\ell} \right\}$$
(11)

This choice for the value assigned to  $x_{k\ell}$  eliminates either row k or column  $\ell$  from the matrix  $\bar{P}$  of payoffs for the next iteration. The new values  $x'_{k'n'}$ ,  $x'_{m'\ell}$  for  $x_{k'n'}$  and  $x_{m'\ell}$  are found as follows:

If

$$x_{k\ell} = \frac{x_{kn'}}{d_{k\ell}}$$

then

$$x'_{kn'} = x_{kn'} - d_k \rho x_k \rho = 0$$

$$x'_{m'} \rho = x_{m'} \rho - x_k \rho$$
(12)

If

$$x_{bp} = x_{m'b}$$

then

$$x'_{kn'} = x_{kn'} - d_k \rho x_{m'} \rho$$

$$x'_{m'} = x_{m'} \rho - x_k \rho = 0$$
(13)

In the first case  $\overline{P}_{new} = \overline{P} - \{c_{kj} | x_{k'n'}' = 0\} \ (j = 1, \ldots, n)$ . In the second case  $\overline{P}_{new} = \overline{P} - \{c_{ij'} | x_{m'j'}' = 0\} \ (i = 1, \ldots, m)$ .

If  $\frac{x_{kn'}}{d_{k\ell}} = x_{m'\ell}$  then an arbitrary decision is made to perturb  $x_{kn'}$  by a small amount epsilon.

The matrix maximum procedure can be terminated in either of two ways, by exhausting the matrix  $\overline{P}$  of payoffs (complete matrix maximum) or by assigning a fixed number (less than the number of iterations required to exhaust the matrix of payoffs) of positive allocations  $x_{ij}$  to be made (partial matrix maximum).

Throughout the matrix maximum iterations exactly m + n elements of the vector  $\overline{X}$  of allocations  $(x_{ij}, x_{in'}, x_{m'j})$  are positive. The vector  $\overline{X}$  satisfies Conditions 7P for primal feasibility.

The matrix maximum procedure proceeds from a vertex of the solution space to a neighboring vertex as does the simplex procedure, but specifically it proceeds to the vertex that has one less positive slack component and one more positive nonslack component (i.e., component having positive cost  $c_{ij}$ ); hence the former is more efficient using a per iteration comparison. The matrix maximum procedure is not sufficient, however, to achieve optimality in general.

#### 2. Solving for Dual Space Variables

The vector  $\overline{X}$ , resulting from application of the matrix maximum process (partial or complete), is a candidate optimizing point since it is an extreme point (Ref 4, p 58) of the convex set K of points  $(x,x_s)'$  satisfying Conditions 7P

$$Ax + 1_{m+1}x_s = b$$
,  $x \ge 0$ ,  $x_s \ge 0$  (7P)

The linearly independent set (a basis) of m + n vectors corresponding to  $X^{\circ} = (x^{\circ}, x^{\circ})$  (the subvector of positive components of  $\overline{X}$ ) is defined as follows:

If 
$$x_{ij} > 0$$
 then  $d_{ij}\vec{e}_i + \vec{e}_{m+j}^{\dagger}$  is a member of the basis

If  $x_{in'} > 0$  then  $\vec{e}_i$  is a member of the basis

(14)

If  $x_{m'j} > 0$  then  $\vec{e}_{m+j}$  is a member of the basis

Recall that in the matrix maximum process if  $x_{ij} > 0$  then not both  $x_{in'} > 0$  and  $x_{m'j} > 0$ ; hence if  $d_{ij}\vec{e}_i + \vec{e}_{m+j}$  is a basis vector then not both  $\vec{e}_i$  and  $\vec{e}_{m+j}$  are basis vectors. Conversely, if both  $x_{in'} > 0$  and  $x_{m'j} > 0$  then  $x_{ij} = 0$ ; hence if  $\vec{e}_i$  and  $\vec{e}_{m+j}$  are basis vectors then  $d_{ij}\vec{e}_i + \vec{e}_{m+j}$  is not. The set of m+n column vectors selected from the matrix  $(A, I_{m+n})$  using Definition 14 and denoted by B (the ordered matrix of such column vectors) is thus linearly independent and satisfies the condition

$$BX^{\circ} = b$$

Hence  $\bar{X}$  is an extreme point of K.

Corresponding to  $X^{\circ}$  satisfying the equation  $BX^{\circ} = b$  is a vector  $w^{\circ}$  satisfying the equation  $B'w^{\circ} = c^{\circ}$  where  $c^{\circ}$  is the vector of costs (payoffs) associated with  $X^{\circ}$ . If the m + n components of w are written  $w = (u_1, \ldots, u_m, v_1, \ldots, v_n)'$  then the scalar form of the equation B'w = c or w'B = c' is

$$d_{ij}u_i + v_j = c_{ij}^{0} \quad \text{if} \quad x_{ij} > 0$$

$$u_i = 0 \quad \text{if} \quad x_{in'} > 0$$

$$v_j = 0 \quad \text{if} \quad x_{m'j} > 0$$
(15)

Solutions to Eqs 15 satisfy Condition 7S,  $\langle w, x_s \rangle + \langle w_s, x \rangle = 0$ . Since  $x_{in'} > 0$  implies  $u_i = 0$  and  $x_{m'j} > 0$  implies  $v_j = 0$  then  $\langle w, x_s \rangle = 0$ . Similarly, if  $x_{ij} > 0$  implies  $w_{s_{ij}} = d_{ij}u_i + v_j - c_{ij} = 0$  then  $\langle w_s, x_s \rangle = 0$ .

#### 3. Optimality Test (Testing Conditions 7D)

The set of necessary and sufficient Conditions 7D required for optimality of  $X^{\circ}$  is rewritten here for reference.

†
$$\vec{c}_i$$
 here is a unit column vector in  $E^{m+n}$ .  
 $\vec{c}_i = (0,0,\ldots,1,0,\ldots,0)'$ .  
 $\longleftarrow_i$ th component

(RAC)

$$\begin{vmatrix}
A^*w - I_{mn}w_s & \leq c \\
w_s & \leq 0 \\
w & \geq 0
\end{vmatrix} (7\overline{D})$$

The scalar form of Conditions 7D is

$$d_{1j}u_1 + v_j - w_{s_{1j}} = c_{1j} + mn \text{ equations}$$

$$w_{s_{1j}} = 0 + mn \text{ inequalities}$$

$$u_1 \ge 0 + v_j \ge 0 + m + n \text{ inequalities}$$
(16)

Let  $(u_1^{\circ}, \ldots, u_m^{\circ}, \nu_1^{\circ}, \ldots, \nu_n^{\circ})'$  be the solution to Eqs 15. Since Eq 16 must hold for optimality we must have  $w_{s_{ij}}^{\circ} \geq 0$ ,  $u_i^{\circ} \geq 0$ ,  $v_j^{\circ} \geq 0$  [(mn + m + n) inequalities] where

$$w_{s_{ij}}^{0} = d_{ij}u_{i}^{0} + v_{j}^{0} - c_{ij}$$
 (17)

If  $w_{s_{ij}}^{o} \geq 0$ ,  $u_{i}^{o} \geq 0$ ,  $v_{j}^{o} \geq 0$  for all i,j then  $X^{o}$  is optimal and the algorithm is terminated. If, however,  $w_{s_{ij}}^{o} < 0$  for some i,j or  $u_{i}^{o} < 0$  or  $v_{j}^{o} < 0$  for some i or j, an improvement in the solution  $X^{o}$  can be made.

### 4. Nonoptimal Solutions; Finding the Greatest Violation of the Dual Space Constraints; Identifying the Associated Vector for Entry into the Primal Solution Space Basis

The greatest violation, V , of the dual space constraints (Conditions  $7\overline{D}$ ) is simply

$$V = \min \left\{ \min_{i,j} \left\{ u_{s_{ij}}^{0} \mid u_{s_{ij}}^{0} < 0 \right\} ; \min_{i} \left\{ u_{i}^{0} \mid u_{i}^{0} < 0 \right\} ; \min_{j} \left\{ v_{j}^{0} \mid v_{j}^{0} < 0 \right\} \right\}$$
 (18)

Depending on which of the above three bracketed minimums is largest in magnitude, the corresponding vector chosen to enter the new basis is one of the three types of vectors  $d_{ij}\vec{e}_i^{\dagger} + \vec{e}_{m+j}^{\dagger}$ ,  $\vec{e}_i^{\dagger}$ , or  $\vec{e}_{m+j}^{\dagger}$ .

### 5. Finding the Representation of the New Basis Vector in Terms of the Current Basis Vectors

Consider the three cases (a)  $V=w_{s_{\bar{1}\bar{1}}}^{o}$ , (b)  $V=u_{\bar{1}}^{o}$ , (c)  $V=v_{\bar{1}}^{o}$  that can result from Eq 18.<sup>†</sup> The vector equation to be solved for a singly indexed system is

$$\vec{A}_k = By_k \quad \text{or} \quad y_k = B^{-1} \vec{A}_k \tag{19}$$

 $<sup>^{\</sup>mathsf{T}}$ The bar denotes the minimizing index or indexes in Eq 18.

where  $y_k$  is the vector of coordinates of  $\vec{A}_k$  relative to the basis of column vectors of B.

Corresponding to cases a, b, or c the following vector equation is solved for  $y_{ij}^{ij}$ , the m + n components of the entering basis vector.

(a) 
$$d_{1j} \vec{e}_{1} + \vec{e}_{m+j}$$
  
(b)  $e_{1}$   
(c)  $\vec{e}_{m+j}$  
$$= \sum_{i,j} y_{ij}^{ij} (d_{ij} \vec{e}_{i} + \vec{e}_{m+j}) + \sum_{i} y_{in}^{ij} \vec{e}_{i} + \sum_{j} y_{m'j}^{ij} \vec{e}_{m+j}$$

$$x_{ij} > 0 \qquad x_{in'} > 0 \qquad x_{m'j} > 0$$
(20)

Equation 20 leads to the following three sets of scalar equations in  $y_{ij}^{\bar{i}\bar{j}}$ ,  $y_{ij}^{\bar{n}'}$ , or  $y_{ij}^{m'\bar{j}}$ :

For Eq 20a

$$\sum_{j} y_{ij}^{\bar{i}\bar{j}} d_{ij} + y_{in}^{\bar{i}\bar{j}} = d_{\bar{i}\bar{j}} \quad \text{if} \quad \bar{i} = \bar{i} \\
x_{ij} > 0 \\
\sum_{j} y_{ij}^{\bar{i}\bar{j}} d_{ij} = 0 \quad \text{if} \quad \bar{i} \neq \bar{i} \\
x_{ij} > 0 \\
\sum_{j} y_{ij}^{\bar{i}\bar{j}} + y_{mj}^{\bar{i}\bar{j}} = 1 \quad \text{if} \quad j = \bar{j} \\
x_{ij} > 0 \\
\sum_{j} y_{ij}^{\bar{i}\bar{j}} + y_{mj}^{\bar{i}\bar{j}} = 0 \quad \text{if} \quad j \neq \bar{j} \\
x_{ij} > 0$$
(21)

For Eq 20b

$$\sum_{j} y_{ij}^{\bar{i}n'} d_{ij} = \begin{cases}
1 & \text{if } i = \bar{i} \\
 & (i = 1, ..., m) \\
0 & \text{if } i \neq \bar{i}
\end{cases}$$

$$\sum_{i} y_{ij}^{\bar{i}n'} = 0 \qquad (j = 1, ..., n)$$

$$x_{ij} > 0$$
(22)

For Eq 20c

$$\sum_{j} y_{i,j}^{m'j} d_{ij} = 0 (i = 1, ..., m)$$

$$x_{ij} > 0$$

$$\sum_{i} y_{i,j}^{m'j} = \begin{cases}
1 & \text{if } j = \overline{j} \\
0 & \text{if } j \neq \overline{j}
\end{cases}$$

$$(23)$$

#### 6. Selecting the Vector To Leave the Current Basis

Once the vector that enters the new basis has been found, the associated positive components of the new primal solution  $\chi_{\text{new}}^{0}$  must also satisfy Conditions 7P for primal feasibility. Hence we have

$$BX^{\circ} = B_{\text{new}}X^{\circ}_{\text{new}} = b \qquad X^{\circ}_{\text{new}} = 0$$
 (24)

or

$$BX^{\bullet} = \theta \begin{cases} (a) & d_{\overline{1}\overline{1}}\vec{c}_{\overline{1}} + \vec{c}_{m+\overline{1}} \\ (b) & \vec{c}_{\overline{1}} \\ (c) & \vec{c}_{m+\overline{1}} \end{cases} + \theta \begin{cases} (a) & d_{\overline{1}\overline{1}}\vec{c}_{\overline{1}} + \vec{c}_{m+\overline{1}} \\ (b) & \vec{c}_{\overline{1}} \\ (c) & \vec{c}_{m+\overline{1}} \end{cases} = b$$
 (25)

$$= BX^{\bullet} - \theta \begin{cases} (a) & By^{\overline{1}\overline{1}} \\ (b) & By^{\overline{1}n'} \\ (c) & By^{\overline{m'}\overline{1}} \end{cases} + \theta \begin{cases} (a) & d_{\overline{1}\overline{1}}\overrightarrow{c_1} + \overrightarrow{c_m}, \overline{1} \\ (b) & \overrightarrow{c_1} \\ (c) & \overrightarrow{c_m}, \overline{1} \end{cases} = b$$
 (26)

$$\begin{array}{c}
B \left\{ \begin{array}{ccc}
(a) & \theta y^{\overline{1}\overline{1}} \\
X^{\circ} - & (b) & \theta y^{\overline{1}n'} \\
(c) & \theta y^{\overline{m'}\overline{1}}
\end{array} \right\} + \theta \left\{ \begin{array}{ccc}
(a) & d_{\overline{1}\overline{1}}\overrightarrow{c_{1}} + \overrightarrow{c_{m,\overline{1}}} \\
(b) & \overrightarrow{c_{\overline{1}}} \\
(c) & \overrightarrow{c_{m,\overline{1}}}
\end{array} \right\} = b$$
(27)

Since  $X_{\text{new}}^{\circ} > 0$  we have in particular (a)  $x_{ij}^{\circ} = \theta > 0$ , or (b)  $x_{in'}^{\circ} = \theta > 0$ , or (c)  $x_{m'j}^{\circ} = \theta > 0$  corresponding to the new basis vector a, b, or c. The remaining m + n - 1 column vectors of  $B_{\text{new}}$  are determined by eliminating that column vector of B whose new associated primal solution component  $x_{ij_{\text{new}}}^{\circ}$  vanishes.

This elimination is accomplished as follows. Writing the expressions in the left braces of Eq 27 in component form, we have

$$\mathbf{x}_{ij_{\text{new}}}^{\mathbf{o}} = \begin{cases} \mathbf{x}_{ij}^{\mathbf{o}} - (\mathbf{b}) \theta \mathbf{y}_{ij}^{\mathbf{o}} \\ \mathbf{x}_{ij}^{\mathbf{o}} - (\mathbf{b}) \theta \mathbf{y}_{ij}^{\mathbf{o}} \\ (\mathbf{c}) \theta \mathbf{y}_{ij}^{\mathbf{o}} \end{bmatrix} & \text{for all } (i,j) \ni \mathbf{x}_{ij} \models 0$$
 (28a)

$$x_{\text{in}'}^{0} = x_{\text{in}'}^{0} - \theta y_{\text{in}'}^{1}$$
 for all  $(i,n') \ni x_{in'} = 0$  (28b)

$$x_{m'j_{new}}^{0} = x_{m'j}^{0} - \theta y_{m'j}^{\dagger\dagger}$$
 for all  $(m', j) \ni x_{m'j} = 0$  (28c)

RAC

Since we want  $x_{ij_{new}}^{o}$ , or  $x_{in'_{new}}$ , or  $x_{m'j_{new}}$  to vanish we select positive  $\theta$  from Eq 29

$$\theta = \hat{\theta} = \min_{i,j} \left\{ \frac{x_{(i)}^{\bullet}}{y_{(i)}^{-1}} \middle| y_{(i)}^{\overline{ij}} > 0 \right\} = \frac{(i-1, \ldots, m')}{(j-1, \ldots, n')}$$
 (29)

If the minimizing indexes in Eq 29 are (i,j) = (p,q) then  $x_{pq_{new}}^{p} = 0$  and  $d_{pq}\vec{c}_{p}^{p} + \vec{e}_{m+q}^{p}$  leaves the basis if  $p \neq m'$  or  $q \neq n'$ ,  $\vec{e}_{p}^{p}$  leaves the basis if a = n', and  $\vec{e}_{m+q}^{p}$  leaves the basis if p = m'.

#### 7. Expressing the Solution in Terms of the New Basis

The new solution  $X_{\text{new}}^{\circ}$  has components expressed by Eqs 28a to 28c with  $\theta = \hat{\theta}$ . In particular, as mentioned before,  $x_{pq_{\text{new}}}^{\circ} = 0$  and  $x_{1\bar{1}\bar{1}}^{\circ} = \hat{\theta}$  for the primal variables associated with the leaving and entering vectors respectively.

#### 8. Return to Step 2

RAC

Self-explanatory.

#### 7. EFFECT OF NEW SOLUTIONS ON VALUE OF OBJECTIVE FUNCTION

There is associated with any violation of Conditions  $7\overline{D}$  a new solution  $(X_{\text{new}}^{\circ})$  to Conditions 7P that improves the value of the objective function  $(c^{\circ}, X^{\circ})$  and at the same time eliminates the specific violation of  $7\overline{D}$ .

Recall from step 6 of the algorithm Conditions 7P are preserved when a new vector  $\vec{A}_k$  enters the basis, thus

$$BX^{\circ} = \theta A_{k} + \theta \overrightarrow{A}_{k} - b$$

$$BX^{\circ} = \theta By_{k} + \theta \overrightarrow{A}_{k} - b \qquad \overrightarrow{A}_{k} = By_{k}$$

$$B(X^{\circ} - \theta y_{k}) + \theta \overrightarrow{A}_{k} - b \qquad (30)$$

For the corresponding expression to the objective function value we have

or 
$$\frac{\langle c^{\bullet}, (X^{\bullet} - \theta y_{k}) \rangle + \theta c_{k}}{\langle c^{\bullet}, X^{\bullet} \rangle - \theta (c_{k} - \langle c^{\bullet}, y_{k} \rangle) \quad \text{(new objective function value)}}$$
(31)

The term  $(c_k - \langle c^0, y_k \rangle)$  corresponds to  $(c_k - z_k)$  in general simplex notation and in the notation of this paper to (a)  $-w_{s_k}$  for  $1 \le k \le mn$  when  $\vec{A}_k = d_{ij}\vec{e}_i \cdot \vec{e}_{m+j}$  k = n(i-1) + j, or (b)  $-u_i$  when  $\vec{A}_k = \vec{e}_i$   $mn \cdot k \le mn \cdot m$ , or (c)  $-v_i$  when  $\vec{A}_k = \vec{e}_{m+j}$ 

mm + m < k < mm + m + n . Thus for positive  $\theta$  and any violation of Conditions  $7\overline{D}$ , i.e.,  $w_{s_k} < 0$ ,  $u_i < 0$ , or  $v_j < 0$ , there is an associated improvement in the objective function value of magnitude (a)  $-\theta w_{s_k}$ , (b)  $-\theta u_i$ , or (c)  $-\theta v_j$  when the vector (a)  $\overrightarrow{A}_k$ , (b)  $\overrightarrow{e}_i$ , or (c)  $\overrightarrow{e}_{m+j}$  enters the new basis. Condition  $7\overline{S}$  guarantees that the violation will be eliminated for the next iteration.

Throughout the algorithm values for  $z_k$  ( $z_k = \langle c^{\circ}, y_k \rangle$ ) are not computed using the  $y_k$  representation of  $\vec{A}_k$  (i.e., the representation relative to basis vectors B), but from the relation  $z_k = \langle w^{\circ}, \vec{A}_k \rangle$  which makes for greater efficiency in computation.

#### 8. COMPUTATIONAL EXPERIENCE

The algorithm briefly called MATMAX was originally used to solve the linear subproblems described in Ref 1 with m = 3, n = 4. During the process of convergence to a single larger nonlinear programming problem solution to which the linear programming Prob 3 is only a constraint, it became necessary to solve the linear problems in the order of ten thousand times. The need for an algorithm faster than the standard simplex algorithm thus arose.

TABLE 1
Solution Times for MATMAX and Standard Simplex Algorithms<sup>a,3</sup>

Number of constraints		MATMAX, sec	Simplex, <sup>7</sup> sec	Simplex, b sec
m	n			
5	4	0.16	0.60	0.36
10	12	5.56	31.51	15.84
18	24	24.88	297.10	114.98

<sup>&</sup>lt;sup>a</sup>Solution times are based on single precision operations in FORTRAN IV using the IBM 7044 computer.

<sup>b</sup>See App C.

The MATMAX algorithm has been compared for solution time with the simplex algorithm<sup>7</sup> and an even faster simplex algorithm given in App C. The A matrix (with identity) requires  $19.988 = 42 \times 474$  storage locations for the m = 18, n = 24 simplex algorithm, thus limiting the size of "incore" comparison of the algorithms. Solution times for MATMAX and standard simplex algorithms are shown in Table 1.

The success of the algorithm currently depends on being able to solve the m + n linear equations Eqs 15 in  $u_i$  and  $v_j$  sequentially, i.e., on solving for the nonzero  $u_i$  and  $v_i$  in terms of zero valued  $u_i$  and/or  $v_j$ .

If, however, it is not possible to solve the system of Eqs 15 sequentially during some iteration of the algorithm, an attempt is made to bypass the difficulty. The algorithm then attempts to proceed to the optimum by avoiding the particular vertex for which Eqs 15 could not be solved. Currently the algorithm returns to phase 1 (the matrix maximum phase), this time assigning one less  $\mathbf{x}_{ij}$  having positive cost  $\mathbf{c}_{ij}$  and one more positive slack variable (partial matrix maximum) than was assigned the prior solution of phase 1. Beginning with this solution in phase 2 (simplex) a new sequence of vertexes is generated for which the problem of nonsequential solvability of Eqs 15 is frequently avoided.

The above process has worked successfully on most problems of moderate size but has failed on one with m = 30, n = 32. In some situations more than one return to phase 1 may be required in order to find a sequence of vertexes for which Eqs 15 may be solved.

It is, of course, possible to solve Eqs 15 when sequential methods fail. However, the logic of loop-tracing techniques required in such situations is complex and is not currently employed. Alternative methods that use the sequential solvability of Eqs 15 as a secondary criterion for selecting the next neighboring vertex are under investigation.

#### COMPUTER PROGRAM FOR THE ALGORITHM

#### INTRODUCTION

A listing of the computer program for the algorithm follows. The algorithm has been used successfully on problems of moderate size (see Sec 8, "Computational Experience"). The comment cards identify appropriate subsections of the program as described in Sec 6, "Details of the Algorithm."

The success of the algorithm currently depends on being able to solve the m + n linear equations Eqs 15 in  $u_i$  and  $v_j$  sequentially, i.e., on solving for the nonzero  $u_i$  and  $v_j$  in terms of zero valued  $u_i$  and/or  $v_j$ , as discussed in "Computational Experience."

Several working arrays are used for calculations; namely, the AE, ABASIS, YY, ABAR, BBAR, U, V, ISUM, and JSUM arrays.

The value of the objective function is printed out every kth iteration by setting IWRITE = k on the first input card. In addition, a detailed printout will be given every kth iteration by setting ITAB = 1 on the same card.

The computer program of App C accepts exactly the same input cards as the following program, with the exception as stated in App C.

The subroutine TODAY called twice in the program is used for timing purpose only. The general user should not call this subroutine.

#### Appendix B

#### SAMPLE PROBLEM

#### **EXAMPLE**

A short example is given here to illustrate (a) the type of problem to which the algorithm can be applied and (b) the details of the solution process. The example with some modifications is taken from Ref 3. The problem is one of allocating several types of commercial aircraft to various routes (e.g., New York to Dallas) in order to maximize overall profit (revenue less operational costs) for the system (see Fig. B1). The problem can be stated as follows:

- Let m denote the total number of routes
  - n denote the total number of types of aircraft
  - $a_i$  denote the anticipated number of passengers on route i per month
  - $b_i$  denote the number of aircraft of type j
  - $d_{ij}$  denote the monthly passenger-carrying capacity of aircraft type i on route i
  - r, denote the revenue per passenger on route i
  - $s_{ij}$  denote the monthly operational cost for operating aircraft type j on route i.

Then we seek to find the allocations  $x_{ij}$  of aircraft type j to route i for the system that maximize profit subject to constraints on the number of anticipated passengers using the various routes and the available number of each type of aircraft.

Specifically maximize profit  $z(x_{ij})$ 

D	Aircraft type j			
Route i	1	2	3	4
1	1600	-		900
2	1500	1000	500	1 100
3	2800	1400		2200
4	2300	1500	700	1700
5	8100	5700	2900	5500

#### a. Aircraft Passenger-Carrying Capacity per Month $(d_{ij})$

D	Aircraft type j			
Route i	1	2	3	4
1	18,000			17,000
2	21,000	15,000	10,000	16,000
3	18,000	16,000		17,000
4	16,000	14,000	9,000	15,000
5	10,000	9,000	6,000	1,000

#### b. Operational Costs in Dollars per Month $(\mathbf{s}_{ii})$

#### Fig. B1—Sample Data for Aircraft Allocation Problem

Blanks in cell i, j indicate that aircraft type j is never assigned to route i.

$$n = 5$$
 (routes)  $n = 4$  (types of aircraft)

Passenger data	Passenger fare data	Aircraft data
$a_1 = 25,000$	r <sub>1</sub> = \$130.00	b <sub>1</sub> = 10
$a_2 = 12,000$	$r_2 = $130.00$	$b_2 = 19$
$a_3 = 18,000$	$r_3 = $70.00$	$b_3 = 25$
$a_4 = 9,000$	$r_4 = $70.00$	$b_4 = 15$
$a_5 = 60,000$	$r_5 = $10.00$	

$$z(x_{ij}) = \underbrace{\sum_{i=1}^{m} r_{i} (\sum_{j=1}^{n} d_{ij} x_{ij})}_{\text{revenue}} - \underbrace{\sum_{i,j}^{m} s_{ij} x_{ij}}_{\text{operational costs}}$$

$$= \underbrace{\sum_{i=1}^{m} \sum_{j=1}^{n} (r_{i} d_{ij} - s_{ij}) x_{ij}}_{\text{ij}}$$
(B1)

subject to

$$\sum_{j=1}^{n} d_{ij} x_{ij} \stackrel{?}{=} a_{i} \qquad (i=1,\ldots,m) \qquad \text{do not exceed passenger demand for each route } i$$

$$\sum_{i=1}^{m} x_{ij} \stackrel{?}{=} b_{j} \qquad (j=1,\ldots,n) \qquad \text{do not exceed aircraft availability for each type } j$$

Data for m = 5, n = 4 are given in Table 1 as taken from Ferguson-Dantzig.<sup>3</sup> It should be noted that if  $c_{ij} = r_i d_{ij} - s_{ij}$  above, then the form of the problem is that of Prob 3. The Ferguson-Dantzig<sup>3</sup> example requires that all aircraft be allocated, i.e.,  $\sum_{i=1}^{m} x_{ij} = b_j$  (j = 1, ..., n). The algorithm here does <u>not</u> require that all resources be allocated. However, at least all the row or all the column constraints will be binding for an optimal solution. If all the column constraints are binding, then of course the equality constraints on the columns are satisfied.

The example of Ferguson-Dantzig<sup>3</sup> can be formulated from the example here for m = 5, n = 4 as follows:

Let

$$x_{15} = a_{1i} - \sum_{j=1}^{4} d_{ij} x_{ij}$$

$$s_{15} = r_{1} \qquad d_{15} = 1$$
(B2)

then we have

$$\max_{x_{ij}} z(x_{ij}) = \max_{x_{ij}} \left\{ \sum_{i=1}^{5} r_i (a_i - x_{i5}) - \sum_{i=1}^{5} \left( \sum_{j=1}^{4} s_{ij} x_{ij} \right) \right\}$$

$$= \max_{x_{ij}} \left\{ \sum_{i=1}^{5} r_i a_i - \left\{ \sum_{i=1}^{5} \left( \sum_{j=1}^{4} s_{ij} x_{ij} + r_i x_{i5} \right) \right\} \right\}$$

$$= \sum_{i=1}^{5} r_i a_i - \min_{x_{ij}} \left\{ \sum_{i=1}^{5} \left( \sum_{j=1}^{5} s_{ij} x_{ij} \right) \right\}$$
(B3)

subject to

$$\sum_{j=1}^{4} d_{ij} x_{ij} + x_{15} = \sum_{j=1}^{5} d_{ij} x_{ij} = a_{i} \qquad (i = 1, ..., 4)$$

$$\sum_{j=1}^{4} x_{ij} = b_{j} \qquad (j = 1, ..., 5)$$

Ferguson and Dantzig<sup>3</sup> consider the problem

$$\min_{\substack{x_{ij} \\ x_{ij} \\ i=1}} 5,5 \\ s_{ij}x_{ij}$$

subject to the two sets of constraints given.

Details of the solution are printed at each step of the solution for the problem expressed by Eq B1. A completely detailed description illustrating the algorithm on a step-by-step basis is presented between the first and second intermediate printouts (iterations) of phase 2 of the algorithm.

#### DETAILED DESCRIPTION OF ONE ITERATION OF PHASE 2

A detailed numerical examination of one iteration of phase 2 of the algorithm is presented here. Given the solution array XX(I,J) of the previous page, we wish to test optimality of the solution. Proceeding as in step 2 of the algorithm we solve Eqs 15 for  $(u_1, \ldots, u_5, v_1, \ldots, v_1)$ .

Since  $x_{63}$  = 6.27586 > 0 and  $x_{51}$  = 2863.63 > 0, we have  $v_3$  = 0 and  $u_1$  = 0 immediately, i.e., we solve for the zero-valued dual-space variables first. The remaining seven equations

$$d_{ij}u_i+v_j-c_{ij} \quad \text{if} \quad \overline{x}_{ij}=0$$

are solved sequentially. We have

Moving on to step 3 of the algorithm the optimality test is now made (i.e., Conditions  $7\overline{D}$  in scalar form of the m+n+mn=29 equalities of Eq 16 are tested). It is seen directly that  $u_i$  ( $i=1,\ldots,5$ ) and  $v_j$  ( $j=1,\ldots,4$ ) are nonnegative. Seven of the remaining mn=20 inequalities; namely,  $w_{s_{ij}}=d_{ij}u_i+v_j-c_{ij}=0$  for  $x_{ij}>0$  (i.e., for  $x_{1i},x_{14},x_{53},x_{52},x_{22},x_{42}$  and  $x_{34}$ ) are equalities, hence only the remaining 20-7=13 values of  $w_{s_{ij}}$  are tested for nonnegativity. Computing directly we have

$$\begin{split} w_{\tilde{S}_{12}} &= d_{12}u_1 + v_2 = c_{12} - (1)(0) + 2793.10 - 0 \\ w_{\tilde{S}_{13}} &= d_{13}u_1 + v_3 - c_{13} - (1)(0) + 0 = 0 \\ w_{\tilde{S}_{21}} &= d_{21}u_2 + v_1 - c_{21} - (1500)(112.207) + 190,000 - 174,000 - 0 \\ w_{\tilde{S}_{23}} &= d_{23}u_2 + v_3 - c_{23} = (500)(112.207) + 0 = 55,000 \\ \end{split}$$

It is seen at this point that the only violation and hence the maximum violation (step 4 of the algorithm) of Conditions  $7\overline{D}$  of Eq 16 is

$$w_{s_{32}} = -55661.42 < 0$$

Hence the solution is not optimal and the vector  $d_{32}\vec{e}_3 + \vec{e}_7$  enters the basis.

The vector selected to leave the basis is determined next, but first it is necessary to determine the components  $y_{ij}^{32}$  of the entering vector  $d_{32}\vec{e}_3 + \vec{e}_7$  in terms of the current basis. The set of m + n = 5 + 4 = 9 linear equations Eq 21 is thus solved (step 5 of the algorithm). We have for the case at hand the following system:

$$y_{11}^{32}(1600) + y_{14}^{32}(900) + y_{15}^{32}(1) = 0$$

$$y_{22}^{32}(1000) = 0$$

$$y_{34}^{32}(2200) = d_{32} = 1400$$

$$y_{42}^{32}(1500) = 0$$

$$y_{52}^{32}(5700) + y_{53}^{32}(2900) = 0$$

$$y_{11}^{32} = 0$$

$$y_{22}^{32} + y_{42}^{32} + y_{52}^{32} = 1$$

$$y_{53}^{32} + y_{63}^{32} = 0$$

$$y_{14}^{32} + y_{34}^{32} = 0$$

RAC

The solution to the foregoing equations is

$$y_{22}^{32} = 0$$
,  $y_{34}^{32} = \frac{1400}{2200}$ ,  $y_{42}^{32} = 0$ ,  $y_{52}^{32} = 1$ ,  $y_{11}^{32} = 0$ ,  $y_{53}^{32} = -\frac{5700}{2000}$ ,  $y_{63}^{32} = \frac{5700}{2900}$ ,  $y_{14}^{32} = -\frac{1400}{2200}$ ,  $y_{15}^{32} = \frac{(-900)(-1400)}{2200}$ 

Thus the entering vector  $d_{32}\vec{e}_3 + \vec{e}_7 = 1400\vec{e}_3 + \vec{e}_7$  can be written as the following linear combination of the current basis vectors.

$$1400\vec{e}_{3} + \vec{e}_{7} = \begin{cases} -\frac{1400}{2200} \left[900\vec{e}_{1} + \vec{e}_{9}\right] + \frac{(-900)(-1400)}{2200} \left[\vec{e}_{1}\right] \\ + \frac{1400}{2200} \left[2200\vec{e}_{3} + \vec{e}_{9}\right] + 1\left[5700\vec{e}_{5} + \vec{e}_{7}\right] \\ -\frac{5700}{2900} \left[2900\vec{e}_{5} + \vec{e}_{8}\right] + \frac{5700}{2900} \left[\vec{e}_{8}\right] \end{cases}$$

The vector now selected to leave the basis is determined from the indexes that yield the minimum in the brackets. Using Eq 29 (step 6 of the algorithm) we have

$$\widehat{\theta} = \min \left\{ \frac{8.18182}{\frac{1400}{2200}} , \frac{1}{1}, \frac{6.27586}{\left(\frac{5700}{2900}\right)}, \frac{2863.64}{\frac{(900)(1400)}{2200}} \right\}$$

and the minimizing indexes are (5,2), since  $\frac{x_{52}}{y_{52}^{32}} = \frac{1}{1}$  yields the minimum value

 $\hat{\theta}$ . Thus the vector  $d_{52}\vec{e}_5 + \vec{e}_7 = 5700\vec{e}_5 + \vec{e}_7$  leaves the basis.

The new solution is evaluated (step 7) using Eqs 28 and appears in the next intermediate printout. The algorithm again returns to step 2 for the next iteration. The value of the objective function was increased by  $\widehat{\theta}(-u_{s_{32}}) = \$55,661.42$  during this iteration.

### Appendix C

### COMPARATIVE SIMPLEX ALGORITHM

This appendix contains a general simplex algorithm programmed specifically to solve Prob 3. The program accepts the same input data as the MATMAX algorithm with the exception of the IWRITE and ITAB information used in the MATMAX algorithm. The algorithm here has been used for comparative purposes, with particular attention given to the times required by the two algorithms to solve the same problem.
